イロト イヨト イヨト イヨト

Eigenfunctions: definition

$$V = \left\{ f : F_q^n \longrightarrow \mathbb{C}
ight\}$$

 $f \leftrightarrow (f(0, \dots, 0), f(0, \dots, 0, 1), \dots, f(q - 1, \dots, q - 1))^T$
 $D - q^n \times q^n, \quad D_{\alpha, \beta} = \left\{ egin{array}{c} 1, &
ho(\alpha, \beta) = 1 \\ 0, & other \end{array}
ight.$ - adjacency matrix of \mathbf{F}_q^n .

Eigenfunction

f is the eigenfunction of \mathbf{F}_q^n with the eigenvalue λ (or λ -function) if

 $Df = \lambda f$.

In other words, $\sum_{\beta \in W_1(\alpha)} f(\beta) = \lambda f(\alpha), \quad \forall \alpha \in \mathbf{F}_q^n.$

The eigenvalues of the graph of *n*-dimensional *q*-ary hypercube are equal to $\lambda_i = (q-1)n - qi, i = 0, 1, ..., n$

Perfect codes: definition

Definition

The code $C \subseteq \mathbf{F}_q^n$ is perfect if

$$\forall \alpha \in \mathbf{F}_{q}^{n} \exists ! \beta \in \mathbf{F}_{q}^{n} \rho(\alpha, \beta) = 1$$

A perfect code intersects with a ball of radius 1 by exactly one vertex. Let χ_C be the characteristic function of Cthen $\chi_C - 1/((q-1)n+1)$ is λ -function with $\lambda = -1$

The number of the eigenvalue for perfect codes

The number of the eigenvalue is $h(-1) = \left((q-1)n+1\right)/q$

Reconstruction of Perfect Binary Codes

 $n = 2^t - 1$ is odd

$$|W_{(n-1)/2}| = |W_{(n+1)/2}| = max_{i=0,1,...,n}|W_i|$$

Reconstruction

Avgustinovich S.V.:

$$C \bigcap W_{(n-1)/2} \rightarrow C$$

The idea: Any perfect binary code is antipodal: $\alpha \in C \iff \mathbf{1} + \alpha \in C$

$$C \cap W_{(n-1)/2} \rightarrowtail C \cap \left(W_{(n-1)/2} \cup W_{(n+1)/2}\right)$$
$$C_1 \neq C_2, \quad C_1 \cap W_{(n-1)/2} = C_2 \cap W_{(n-1)/2}$$
$$\left(C_1 \cap \left(W_0 \cup W_1 \cup \ldots \cup W_{(n+1)/2}\right)\right) \cup \left(C_2 \cap \left(W_{(n+1)/2} \cup \ldots \cup W_n\right)\right)$$

$\lambda\text{-functions:}$ binary case

Any λ -function code is antipodal or minus-antipodal: $f(\alpha) = \pm f(\alpha)$

Reconstruction

As in case of perfect codes: $f(\alpha), \alpha \in W_m \implies f(\alpha), \alpha \in \mathbf{F}_{q^{\prime}}^n$ where $m = (n \pm 1)/2$

 V_h denotes the space of all λ -functions with $\lambda=n-2h$

$$V_h = \langle f^{lpha}(eta) = (-1)^{lphaeta}$$
 : $wt(lpha) = h
angle$

Krawtchouk polynomials

$$(x-y)^{t}(x+(q-1)y)^{N-t} = \sum_{m=0}^{N} P_{m}^{(q)}(t;N)y^{m}x^{N-m},$$
$$P_{m}^{(q)}(t;N) = \sum_{j=0}^{m} (-1)^{j}(q-1)^{m-j} {t \choose j} {N-t \choose m-j} -$$

Krawtchouk polynomial

Anastasia Yu. Vasil'eva (Sobolev Institut Are q-ary Perfect Codes reconstructed by

< 行い

$\lambda\text{-functions:}$ binary case

$$\lambda, \quad h=h(\lambda)=(n-\lambda)/2, \ f$$
 - λ -function.

Reconstruction $f(\alpha), \alpha \in W_h \implies f(\alpha), \alpha \in \mathbf{F}_q^n$ in case $P_h(h; n), \dots, P_{h-k}(h-k; n-2k), \dots, P_0(0; n-2h)$ are nonzero.

Reconstruction

Let $d \leq h$. Then $f(\alpha), \alpha \in W_d \implies f(\alpha), \alpha \in B_d$ if $P_d(h; n), \dots, P_{d-k}(h-k; n-2k), \dots, P_0(h-d; n-2h)$ are nonzero.

Let λ be an eigenvalue of the hypercube \mathbf{F}_q^n and $d \leq l(\lambda)$. We know the values $f(\alpha)$ for all α with Hamming weight d. Question: Is it possible to determine (uniquely) the values $f(\alpha)$ for all α with Hamming weight less than d? Obviously,

$$\sum_{\alpha \in W_d} f(\alpha) = P_d^{(q)}(h; n) f(\mathbf{0}).$$

Then

$$f(\mathbf{0}) = \frac{\sum_{\alpha \in W_d} f(\alpha)}{P_d^{(q)}(h; n)}$$

if $P_d^{(q)}(h; n) \neq 0$.

 $f(\alpha), \alpha \in W_d$ – are known

Theorem

Let λ be an eigenvalue of $\mathbf{F}_{q'}^{n}$, n-h < h, $d \leq h$ and $\varphi : W_d \longrightarrow C$ be a function. Suppose that f is a λ -function such that for any $\alpha \in W_d$ it holds $f(\alpha) = \varphi(\alpha)$. Then for any $\alpha \in B_d$ the value $f(\alpha)$ is uniquely determined if for all $k = 0, \ldots, d$ and $l = 0, \ldots, k$

$$\sum_{i=0}^{k} r_{i,d-k}^{k} P_{i}^{(q-1)}(I,k) \neq 0, \qquad (1)$$

where r_{ii}^k is defined in terms of Krawtchouk polynomials.
